

Oribatid mites (Acari, Oribatida) from the biodiversity days in South Tyrol (Prov. Bolzano, Italy)

Abstract

An overview of the oribatid mite fauna collected during the last 14 events „days of biodiversity“ in different regions of South Tyrol from 2003 until 2016 is presented. Collections were undertaken at different altitudes from 270 m to 2300 m a.s.l. in 60 sites belonging to different habitats, as riparian forests, marsh and peat bogs, dry grasslands, scree slopes, montane forests, meadows and pastures, dwarf shrub heaths. Also some microhabitats as lichens on tree bark as well as submerged algae were sampled. A total of 311 oribatid species from 60 families were identified, among them 144 new records for South Tyrol and 41 for Italy. Two species are considered as alpine endemic, most of the other species have a wide distribution. More than 60 species occur preferably in southern Europe or in the southern Palaearctic respectively. The habitats were clustered into three groups: arid, humid, and montane forests including subalpine habitats. Their respective species assemblages are discussed. The highest species numbers were found in the montane forests and larch pastures.

Keywords: Acari, Oribatida, biodiversity days, faunistics, species assemblages, South Tyrol, Italy

Introduction

The original aim of the „day of biodiversity“ is to make an inventory of the environment of human settlements by registering as many plants and animals as possible in a certain area within 24 hours. The background for these activities is to demonstrate the biodiversity in peoples proximate environment and to inspire consciousness for the importance of conservation. The campaign originated in the United States and spread to Europe in 1999, promoted by the German popular magazine GEO. Since then, this day of field research occurs every year in different countries with an increasing number of participants and experts covering numerous animal and plant taxa. On the same day several popular events are arranged for children, school classes, environmental organisations etc. to propagandize the importance of the nearest environment (www.geo.de).

In South Tyrol, the biodiversity day took place in different parts of the country since 2000 (Fig. 1, Table 1). The participants are interested nature lovers but primarily experts in different research fields as mycology, lichenology, bryology, botany, aquatic biology, gastropodology, acarology, arachnology, entomology, herpetology, ornithology, chiropterology, and other taxa. Especially for smaller organisms the presentation of the results was not always possible immediately after the date of the biodiversity day, since the study and identification of the collected taxa took weeks or even months. Results were published in the journal of the South Tyrol Museum of Natural History „*Gredleriana*“. The obtained data are integrated into the database of the museum. Oribatid mites were collected and studied on those occasions since 2003. The present compilation gives an overview and recapitulation of results until present.

Biodiversity days in South Tyrol and collected sites

On the first three days of biodiversity (2000, 2001, 2002) no oribatid mites were collected. Starting from 2003 all results were published (Table 1). On the different events several sites were included in the investigation area, as riparian forests, wet meadows and peat bogs, dry grasslands, montane forests and subalpine meadows. Samples for oribatid mites were taken in a total of 60 sites in different habitats (see table 3). The events took place at different altitudes. The lowest site was a riparian forest at the mouth of Talvera near Bolzano at 270 m a.s.l. All other sites were above 800 m until 2300 m a.s.l. (a subalpine meadow in the Dolomites). High alpine sites were not visited during the biodiversity days.

Results and Discussion

Species

General

During all biodiversity events a total of 311 oribatid mite species belonging to 60 families were collected (Table 2). Families with the highest species numbers overall are Oppiidae (27 spp.), Suctobelbidae (23 spp.), Ceratozetidae (22 spp.), Damaeidae (18 spp.), Brachychthoniidae (14 spp.), Scheloribatidae, Phenopelopidae (12 spp. each), Galumnidae, Oribatulidae, Phthiracaridae (11 spp. each). Thus, more than half of all species belong to one of these ten families.

The species number varies among the different events, depending from the intensity of collecting and number or structure of habitats. In most years between 90 and 140 species were recorded, highest numbers in #16 Val Mazia (4 habitats, 137 spp.) #10 Val di Plan (5 habitats, 133 spp.), #15 Val Sarentino (4 habitats, 129 spp.), #08 Resia (4 habitats, 128 spp.), #12 Val Ridanna (7 habitats, 126 spp.), #09 Valle di Tures (6 habitats, 121 spp.) (Fig. 2).

biodiversity event	03	04	05	06	07	08	09	10	11	12	13	14	15	16	total
species total	23	41	72	92	91	128	121	133	91	126	112	94	129	137	311
new records for Italy	1	0	6	2	10	6	3	5	2	3	3	0	0	1	41
new records for South Tyrol (incl. new for Italy)	6	11	26	25	23	11	13	8	5	6	4	1	5	2	144

Only two species were found on all 14 events (*Phthiracarus laevigatus*, *Scheloribates laevigatus*), four species during 13 events (*Atropacarus striculus*, *Chamobates pusillus*, *Suctobelbella subcornigera*, *Trichoribates berlesei*). On the other hand, 37 spp. were found during two events and 88 spp. only once. The highest number of exclusive species was recorded in #09 Valle di Tures. Also #11 Val Monastero and #16 Val Mazia have high numbers of species restricted to these areas.

Taxonomic update

While working on this compilation some synonymies and nomenclatural unclarities were detected which differ from the hitherto published data:

- *Anachipteria alpina* (SCHWEIZER, 1922) nec HALBERT, 1915, is a homonym, replaced by *A. shtanchaevae* SUBÍAS, 2009
- *Chamobates borealis* (TRÄGÅRDH, 1902) considered as synonym of *Ch. pusillus* (BERLESE, 1895), according to MAHUNKA & MAHUNKA-PAPP (1995)
- *Chamobates spinosus* SELLNICK, 1928 *sensu auct.* considered as synonym of *Ch. rastratus* (HULL, 1914) according to MAHUNKA & MAHUNKA-PAPP (2004)
- *Coronoquadroppia gumista* (GORDEEVA & TARBA, 1990): records in the Alps (#09) considered as synonym of *C. monstruosa* (HAMMER, 1979) according to WEIGMANN & SCHATZ (2015)
- *Coronoquadroppia parallela* OHKUBO, 1995: record in the Alps (#10) considered as synonym of *C. monstruosa* (HAMMER, 1979)
- *Nothrus biciiliatus* C.L. KOCH, 1841 *sensu* WILLMANN (1931) considered as synonym of *N. anauniensis* CANESTRINI & FANZAGO, 1876 according to WEIGMANN (2006)
- *Trichoribates trimaculatus* (C.L. KOCH, 1835) *sensu* SELLNICK (1928) considered as unavailable name, replaced by *Trichoribates berlesei* JACOT, 1929 according to WEIGMANN & NORTON (2009)
- *Zygoribatula exarata* BERLESE, 1916 *lapsus* in HÖPPERGER & SCHATZ (2013) is *Zygoribatula excavata* BERLESE, 1916

New records

Overall 41 species (including 2 unidentified species) were first recorded for Italy. The highest number of new records for Italy was found in #07 Sciliar – Sassopiatto in the Dolomites. Additional 103 species were not found in South Tyrol before the respective event which gives a total of 144 new records for South Tyrol. The majority of new records were found in the families Oppidae (20 spp.), Ceratozetidae (12 spp.), Suctobelbidae (9 spp.), Brachychthoniidae, Damaeidae, Scheloribatidae (7 spp. each). A possible explanation for the prominence of these families could be that most of these families (except Oppidae) contain Central European or alpine species which do not occur in the warmer parts of Italy.

General distribution

Fig. 3 shows the general distribution of the species encountered in all biodiversity events. Most species have a wide distribution. Species with palaearctic (87 spp., 28%) and holarctic distribution (94 spp., 30%) provide more than half of all species. Above the Holarctic region („(semi)cosmopolitan“: in common also with the Neotropical region or New Zealand) 58 spp. (18,6%) are known. A total of 70 species (22,5%) are reported from Europe, among them 14 spp. (4,5%) are restricted to central Europe, and 34 spp. (10,9%) to central-south Europe. Two species (*Kunstidamaeus tecticola*, *Trichoribates scilierensis*) can be considered as alpine endemic. Two species could not be identified at species level (*Eupelops* sp., *Tectocepheus* sp.), possibly they are new for science. More than 20% of all species can be considered as „southern species“. Their distributional focus lies in south and southeast Europe, around the Mediterranean Sea or around the Black and Caspian Sea. Some of them occur also in the southern Palaearctic region in dry grasslands, steppes or semideserts (SCHUSTER 1959, TARMAN 1977, BAYARTOGTOKH et al. 2011). In South Tyrol this species group was also mainly encountered in dry grassland (see below).

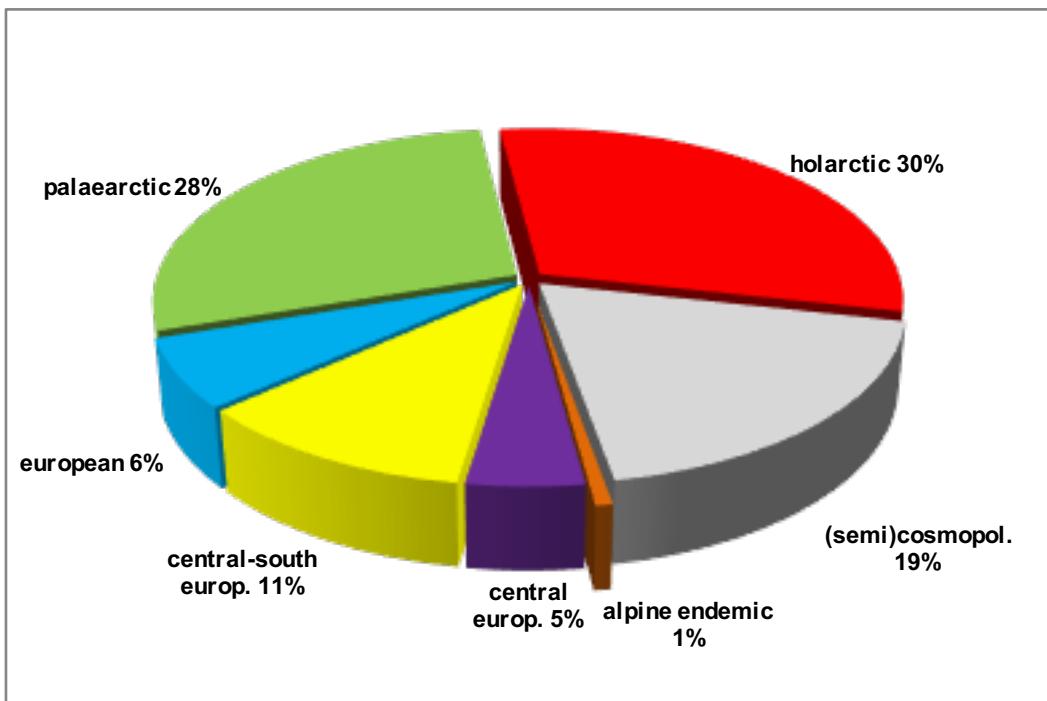

Fig. 3: Oribatid mites (Acari: Oribatida) from the biodiversity days in South Tyrol (Italy). General distribution of the species (309 spp. = 100%, 2 undetermined species omitted)

Habitats

On most biodiversity events different habitat types in a defined area were offered. Additional samples were taken from lichens on tree bark and in a pool as a sample of submerged algae. Habitats with oribatid mite collections are listed in Table 3. This table lists also the species number found in each habitat. The habitats can be clustered roughly into 12 habitat types which belong to 3 larger units (arid, humid habitats, montane forests and subalpine habitats) (Table 4).

Table 3: Biodiversity days („GEO-Tage der Artenvielfalt“) in South Tyrol (Prov. Bolzano, Italy). Sites (habitats) collected, altitude, total number of oribatid species on each biodiversity day and number of oribatid species in each site.

wet meadow colline	1	830	37	moist pasture (#09)
wet meadows montane	3	1460 - 2050	63	moist meadows until swampy meadow
bogs	8	835 - 1775	123	
Montane forests and subalpine habitats:				
montane forests	13	870 - 1910	189	incl riparian forest in the montane zone (#06), submerged habitat in a pool (#12), environment of a cold air pool cave (#09)
subalpine meadows	6	1617 - 2300	116	incl subalpine pastures
Rhododendron bushes and dwarf shrub heath	3	1650 - 2036	126	
bark on trees, lichens	4	1500 - 2060	43	

Arid habitats

The colline dry grassland (#04, #05, 860 – 910 m a.s.l.) has a slightly different species composition than the montane dry grassland which reaches 1900 m a.s.l. (Foto 1). Collections in dry grassland were mainly carried out in the Vinschgau and side valleys (#08, #10, #11, #12, #16) but also in the Dolomites (#06). More than a third of the species in these areas are known to be xerophilous, among them *Ceratozetes minutissimus*, *Micozetorches tes emeryi* (both species restricted to these sites), *Eueremaeus valkanovi*, *Licnodamaeus pulcherrimus*, *Passalozetes* spp., *Poecilochthonius italicus*, *Ramusella mihelcici*, *Scutovertex* spp., *Verachthonius laticeps*.

The species composition of the larch forests can be compared in some respects with the montane dry grassland. These scattered forests contain agriculturally used meadows and pastures, frequently with arid character (Foto 2). Some noteworthy oribatid species recorded from this habitat are *Camisia biverrucata* (with arboricolous juvenile stages), *Haplozetes vindobonensis*, *Micreremus brevipes*, *Peloribates longipilosus*, *Phauloppia nemoralis*, *Ramusella insculpta*, *Suctobelbella arcana*, *Xenillus salamoni*. The rare species *Tricheremaeus travei* was found only in this habitat in #08 (SCHATZ 2009).

Scree slopes are a particularly remarkable habitat type with extreme microclimatic conditions, due to sun exposed rocks, lack of water and little soil formation. The surface of the rocks is sometimes covered with lichens or dry moss (Fotos 3, 4). Specialised, frequently xerophilous or alpine oribatid species were found in this harsh environment, e.g. *Eupelops variatus*, *Kartoeremaeus areolatus*, *Lamellovertex caelatus*, *Licnodamaeus pulcherrimus*, *Mycobates alpinus*, *Phauloppia pilosa*, *Pseudoppia mediocris*, *Tectocepheus* sp., *Trichoribates scilierensis*. In Val Monastero (#11) a mixed forest on a scree slope with *Quercus pubescens*, *Larix decidua*, *Betula pendula* and other trees and bushes (Foto 5) represents an intermediate stage to mature soils with slightly advanced colonisation by oribatid species (71 spp. vs. 28 – 51 spp. in other scree slopes). The undescribed species *Tectocepheus* sp. was detected for the first time on a large scree slope on the Sasso Piatto / Plattkofel (#07, Foto 6) and subsequently in different montane areas. Additional findings suggest that this species might be endemic to higher altitudes of the Central Alps.

Humid habitats

Most collections in riparian forests (Foto 7) were carried out at lower altitudes (an exception of the riparian forest in #06 at 1800 m a.s.l. contains a species composition of the surrounding montane forests and was included in that habitat type). These forests have humid soil, are sometimes or regularly inundated and offer appropriate conditions for species with different habitat requirements (47% eurytopic, 76% silvicolous, 26% xerophilous, 24% hygrophilous¹). The edge of a pool in the riparian forest of #09 near Brunico (Foto 8) shows the same species composition as the adjacent forest with mainly silvicolous or hygrophilous species.

Colline (#09, 830 m a.s.l.) and montane moist and wet meadows (1460 – 2050 m a.s.l.) have a species similarity of 40%. These meadows (Foto 9) consist of a mosaic of dry and moist conditions in small space, frequently traversed by rivulets, and the oribatid species composition is accordingly diverse. Hygrophilous (44%) and xerophilous (10%) species occur in these habitats. Some remarkable findings are the hygrophilous species *Mainothrus badius*, *Puncitoribates sellnicki*, *Tegoribates latirostris*, or the xerophilous species *Synchthonius elegans*.

The marshes and peat bogs (Fotos 10, 11, 12) are mainly inhabited and dominated by hygrophilous or even aquatic species as *Astegistes pilosus*, *Eupelops hygrophilus*, *E. strenzkei*, *Galumna obvia*, *Hydrozetes lacustris*, *Limnozetes ciliatus*, *Malaconothrus monodactylus*, *Melanozetes meridianus*, *Nanhermannia comitalis*, *N. nana*, *N. sellnicki*, *Nothrus palustris*, *N. pratensis*, *Oromurcia sudetica*, *Scheloribates (Topobates) circumcarinatus*, *Trhypochthoniellus longisetus*, *Tyrphonothrus glaber*, *T. maior*, *Zetomimus furcatus*, but even there several species with other habitat requirements can be found (54% hygrophilous, 27% tyrphophilous, 23% xerophilous, 67% silvicolous).

A sample of submerged algae and moss in the small pond „Hilbenlacke“ (#12, Val Ridanna, 1507 m a.s.l.) revealed 24 oribatid species. Beside four truly aquatic species (*Hydrozetes lacustris*, *Limnozetes ciliatus*, *L. rugosus*, *Tyrphonothrus maior*) mainly other hygrophilous or tyrphophilous (45%), but also silvicolous (62%) and arboricolous species (25%) were found. Apparently the latter species had fallen into the pond from the trees of the surrounding montane forest.

Montane forests and subalpine habitats

Montane forests (Fotos 13, 14) were the most frequently sampled habitats during all biodiversity events (13), and reach the highest number of species (189) among all habitat types. They harbour species with differing ecological requirements. Beside numerous silvicolous (69%), arboricolous (20%) and xerophilous species (28%, among them *Arthrodamaeus femoratus*, *Eremaeus hepaticus*, *Ophidiotrichus tectus*, *Pseudoppia mediocris*, *Zygoribatula excavata*), hygrophilous (30%, among them *Belba corynopus*,

¹ It should be noted that many species have more habitat requirements and appear in different categories (see Table 2). Regarding the use of the terms „xerophilous“ versus „xerobiontic“ see HÖPPERGER & SCHATZ (2013).

Berniniella conjuncta, *Sellnickochthonius zelawaiensis*, *Suctobelbella hamata*, *S. longirostris*, *S. perforata*, *S. singularis*) or alpine species (14%, among them *Eulohmannia ribagai*, *Mycobates carli*, *Niphocepheus nivalis*, *Steganacarus herculeanus*, *Trhypochthonius cladonicolus*) were found.

A sample of organic litter around a cold air cave near Gais in Val di Tures (#09, 870 m a.s.l., Foto 15) contains a species composition similar to higher montane forests, despite the low altitude. Cold air pools or ice caves are caused by down-slope, cold air streams in a scree slope during the warmer season. The out-flowing air at the lower edge of the talus is strongly cooled down compared with the temperature in the environment, forming extrazonal permafrost. As a result, the vegetation around the caves at the base of the talus contains high alpine elements (BURGA et al. 2005, PUNZ et al. 2005, BRUNNER et al. 2012). This pattern appears also among the oribatid mites: *Fuscozetes intermedius*, *Niphocepheus nivalis*, *Oribatella longispina*, *Oribatula interrupta*, *Trichoribates scilierensis* occur predominantly in the alpine belt.

Subalpine meadows and pastures (Fotos 16, 17) were sampled up to 2300 m a.s.l. (#07 Sasso Piatto / Plattkofel). The percentage of „alpine species“ increases slightly (17%), also hygrohilous (28%) and xerophilous species (27%) are represented in considerable numbers as well as muscicolous (31%) and lichenicolous species (10%). Some remarkable findings in this habitat are *Cepheus tuberculatus*, *Epidamaeus tetricus*, *Euphthiracarus monodactylus*, *Kartoeremaeus areolatus*, *Liocthonius simplex*, *Melanozetes interruptus*, *Mycobates bicornis*, *Niphocepheus nivalis*, *Oppiella maritima*, *O. splendens*, *Pantelozetes alpestris*.

Dwarf shrub heaths and *Rhododendron* bushes (Foto 18) are mixed into the montane forests but reach also above the timber line. The species composition resembles the montane forests (60%), and the number of silvicolous species (79%) in this habitat is noteworthy. The organic debris and humus layer under the bushes is deeper than in the meadows, sometimes even deeper than in the forests.

Special samples were taken from arboricolous lichens and bark from trees, mostly at about 1,5 m above ground. They contain mainly specialized arboricolous, corticolous and lichenicolous species as *Camisia horrida*, *Cymbaeremaeus cymba*, *Dorycranosus curtipilis*, *Micreremus brevipes*, *Mycobates parmeliae*, *Phauloppia lucorum*, *Ph. nemoralis*, *Scheloribates ascendens*.

Conclusions

This compilation is intended as an overview of all results on oribatid mites of the biodiversity days in South Tyrol (2003 – 2016). Records from the respective events were already published, some nomenclatural and taxonomical updates could be clarified. It is shown that the collections on the biodiversity days, which were initially projected as one-day events, contain considerably more information than expected. Although the different sites were selected based on their attractiveness and diverse habitat structure, the results demonstrate some patterns regarding species composition and diversity. The number of new records for South Tyrol is remarkable. It should be kept in mind that some habitats were not or rarely investigated yet, especially the higher alpine areas which constitute a large part of the country. Future collections are necessary to add to the picture of oribatid mite diversity in South Tyrol.

Zusammenfassung

Hornmilben (Acari, Oribatida) von den „Tagen der Artenvielfalt“ in Südtirol (Prov. Bozen, Italien)

Diese Arbeit gibt einen Überblick über die Oribatidenaufsammlungen der letzten 14 Veranstaltungen „Tage der Artenvielfalt“ in verschiedenen Regionen Südtirols zwischen 2003 – 2016. Die Aufsammlungen erstreckten sich von 270 m bis 2300 m ü.M. in 60 Flächen in verschiedenen Lebensräumen, wie Auwälder, Moore, Trockenrasen, Felsstürze, Bergwälder, Bergwiesen und -weiden und Zergstrauchheiden. Auch Rinde und Flechten von Bäumen sowie Moos und Algen aus einem Tümpel wurden gesammelt. Insgesamt wurden 311 Oribatidenarten aus 60 Familien identifiziert, darunter 144 Neumeldungen für Südtirol und 41 für Italien. Zwei Arten weisen ein alpin-endemisches Verbreitungsmuster auf, die meisten der anderen Arten sind weit verbreitet. Mehr als 60 Arten haben ihr Verbreitungszentrum in Südeuropa bzw. in der südlichen Palaarktis. Die einzelnen Lebensräume werden in drei Gruppen zusammengefasst: „trockene, feuchte Lebensräume sowie Bergwälder und subalpine Lebensräume“. Ihre jeweiligen Artenzusammensetzungen werden besprochen. Die höchsten Artenzahlen wurden in den Bergwäldern sowie in den Lärchenweiden gefunden.

Riassunto

Oribatidi (Acari, Oribatida) delle „giornate della biodiversità“ in Alto Adige (Prov. di Bolzano, Italia)

Viene fornita una panoramica della fauna di oribatidi raccolti durante le ultime 14 „giornate della biodiversità“ in varie regioni dell’ Alto Adige dal 2003 al 2016. I rilievi erano stati effettuati in 60 siti con vari habitat, specialmente boschi ripariali, paludi, prati aridi, ghiaioni, boschi montani, pascoli subalpini e fasce a arbusti nani, da 270 m a 2300 m di altitudine. Inoltre sono stati esaminati alcuni microhabitat come licheni su cortecce e alghe sommerse. In totale sono state censite 311 specie di 60 famiglie, fra quali 144 nuove segnalazioni per l’Alto Adige e 41 per l’Italia. Due specie sono considerate endemiche delle Alpi, mentre la maggioranza delle specie mostra una distribuzione ampia. Più di 60 specie possiedono una distribuzione prevalentemente mediterranea o paleartica meridionale. Gli habitat vengono riuniti in tre gruppi: aridi, umidi e di boschi montani compresi habitat subalpini; vengono discusse le rispettive associazioni di specie. La diversità massima è stata rilevata nei boschi montani e nei pascoli con larici.

Acknowledgements

Thanks to the South Tyrol Museum of Natural History, the Department for Nature, Landscape and Natural Environment of the Autonomous Province Bolzano – South Tyrol for the organisation of the biodiversity days and the collection permits, and the Institutes of Zoology and Ecology, Leopold-Franzens University of Innsbruck, Austria for logistical support. Thanks also to the respective communities and organisations for the phantastic catering, („marend“) at the end of each event and to all colleagues and friends who helped me with support by collecting the material. Special thanks to Barbara M. Fischer who contributed a lot of energy and knowledge into the different events and resulting publications, and to my wife Irene Schatz for her continuous support of my work.
